```

[`Object.is`](https://developer.mozilla.org/en-US/docs/Web/JavaScript/Reference/Global_Objects/Object/is).
 * This is extended further to allow Objects to describe the values they * represent, by way of `valueOf` or
 `equals` (and `hashCode`),.
 * Note: because of this extension, the key equality of Immutable.Map and the
 * value equality of Immutable.Set will differ from ES6 Map and Set.
 * ### Defining custom values
 * The easiest way to describe the value an object represents is by implementing
 * `valueOf`. For example, `Date`
 represents a value by returning a unix
 * timestamp for `valueOf`:

```
var date1 = new Date(1234567890000); // Fri Feb 13 2009 ...
var date2 = new Date(1234567890000);
date1.valueOf(); // 1234567890000
assert( date1 !== date2 );
assert( Immutable.is( date1, date2 ) );
```

 * Note: overriding `valueOf` may have other implications if you use this object
 * where JavaScript expects a primitive, such as implicit string coercion.
 * For more complex types, especially collections,
 implementing `valueOf` may
 * not be performant. An alternative is to implement `equals` and `hashCode`.
 * `equals` takes another object, presumably of similar type, and returns true
 * if the it is equal. Equality is
 symmetrical, so the same result should be
 * returned if this and the argument are flipped.

```
assert( a.equals(b) === b.equals(a) );
```

 * `hashCode` returns a 32bit integer number representing the object which
 will
 * be used to determine how to store the value object in a Map or Set. You must
 * provide both or neither
 methods, one must not exist without the other.
 * Also, an important relationship between these methods
 must be upheld: if two
 * values are equal, they *must* return the same hashCode. If the values are not
 * equal, they might have the same hashCode; this is called a hash collision,
 and while undesirable for
 performance reasons, it is acceptable.

```
if (a.equals(b)) {
  assert( a.hashCode() === b.hashCode() );
}
```

 * All Immutable collections implement `equals` and `hashCode`.

`Buffer.TYPED_ARRAY_SUPPORT`:\n *\n * === true Use Uint8Array implementation (fastest)\n *\n * === false
Use Object implementation (most compatible, even IE6)\n *\n * Browsers that support typed arrays are IE 10+,
Firefox 4+, Chrome 7+, Safari 5.1+,\n *\n * Opera 11.6+, iOS 4.2+.\n *\n * Due to various browser bugs, sometimes the
Object implementation will be used even\n *\n * when the browser supports typed arrays.\n *\n * Note:\n *\n * -
Firefox 4-29 lacks support for adding new properties to `Uint8Array` instances,\n *\n * See:
https://bugzilla.mozilla.org/show\_bug.cgi?id=695438.
\n *\n * - Chrome 9-10 is missing the
`TypedArray.prototype.subarray` function.\n *\n * - IE10 has a broken `TypedArray.prototype.subarray` function
which returns arrays of\n *\n * incorrect length in some situations.\n *\n * We detect these buggy browsers and set
`Buffer.TYPED_ARRAY_SUPPORT` to `false` so they\n *\n * get the Object implementation, which is slower but
behaves correctly.\n *\n * \n\nBuffer.TYPED_ARRAY_SUPPORT = global.TYPED_ARRAY_SUPPORT !==
undefined\n\n ? global.TYPED_ARRAY_SUPPORT\n\n : typedArraySupport()\n\n/>\n * Export kMaxLength after
typed array support is determined.\n *\n * \n\nexports.kMaxLength = kMaxLength()\n\n\nfunction typedArraySupport ()

```

a transform stream is a readable/writable stream where you do something with the data. Sometimes it's called a "filter", but that's not a great name for it, since that implies a thing where some bits pass through, and others are simply ignored. (That would be a valid example of a transform, of course.) While the output is causally related to the input, it's not necessarily symmetric or synchronous transformation. For example, a zlib stream might take multiple plain-text writes(), and then emit a single compressed chunk some time in the future. Here's how this works: The Transform stream has all the aspects of the readable and writable stream classes. When you write(chunk), that calls _write(chunk,cb) internally, and returns false if there's a lot of pending writes buffered up. When you call read(), that calls _read(n) until there's enough pending readable data buffered up. In a transform stream, the written data is placed in a buffer.

When `_read(n)` is called, it transforms the queued up data, calling the buffered `_write` cb's as it consumes chunks. If consuming a single written chunk would result in multiple output chunks, then the first outputted bit calls the readcb, and subsequent chunks just go into the read buffer, and will cause it to emit 'readable' if necessary. This way, back-pressure is actually determined by the reading side, since `_read` has to be called to start processing a new chunk. However, a pathological inflate type of transform can cause excessive buffering here. For example, imagine a stream where every byte of input is interpreted as an integer from 0-255, and then results in that many bytes of output. Writing the 4 bytes `{ff,ff,ff,ff}` would result in 1kb of data being output. In this case, you could write a very small amount of input, and end up with a very large amount of output. In such a pathological inflating mechanism, there'd be no way to tell the system to stop doing the transform. A single 4MB write could cause the system to run out of memory. However, even in such a pathological case, only a single written chunk would be consumed, and then the rest would wait (un-transformed) until the results of the previous transformed chunk were consumed.
