Creates an IOHandler subtype that sends model artifacts to HTTP server.\n * An HTTP request of the
`multipart/form-data` mime type will be sent to the\n * `path` URL. The form data includes artifacts that represent
the topology\n * and/or weights of the model. In the case of Keras-style `tf.Model`, two\n * blobs (files) exist in
form-data:\n * - A JSON file consisting of `modelTopology` and `weightsManifest`.\n * - A binary weights file
consisting of the concatenated weight values.\n * These files are in the same format as the one generated by\n *
[tfjs_converter](https://js.tensorflow.org/tutorials/import-keras.html).\n * The following code snippet
exemplifies

```

the client-side code that uses this function:

```

const model = tf.sequential();
model.add(tf.layers.dense({units: 1, inputShape: [100], activation: 'sigmoid'}));
const saveResult = await model.save(tf.io.http('http://model-server:5000/upload', {requestInit: {method: 'PUT'}}));
console.log(saveResult);

```

If the default `POST` method is to be used, without any custom parameters such as headers, you can simply pass an HTTP or HTTPS URL to `model.save`:

```

const saveResult = await model.save('http://model-server:5000/upload');

```

The following GitHub Gist <https://gist.github.com/dsmilkov/1b6046fd6132d7408d5257b0976f7864> implements a server based on [flask](https://github.com/pallets/flask) that can receive the request. Upon receiving the model artifacts via the request, this particular server reconstitutes instances of [Keras Models](https://keras.io/models/model/) in memory.

@param path A URL path to the model. Can be an absolute HTTP path (e.g., `http://localhost:8000/model-upload`) or a relative path (e.g., `./model-upload`).

@param requestInit Request configurations to be used when sending HTTP request to server using `fetch`. It can contain fields such as `method`, `credentials`, `headers`, `mode`, etc. See <https://developer.mozilla.org/en-US/docs/Web/API/Request/Request> for more information. `requestInit` must not have a body, because the body will be set by TensorFlow.js. File blobs representing the model topology (filename: 'model.json') and the weights of the model (filename: 'model.weights.bin') will be appended to the body. If `requestInit` has a `body`, an Error will be thrown.

@param loadOptions Optional configuration for the loading. It includes the following fields:

- weightPathPrefix** Optional, this specifies the path prefix for weight files, by default this is calculated from the path param.
- fetchFunc** Optional, custom `fetch` function. E.g., in Node.js, the `fetch` from node-fetch can be used here.
- onProgress** Optional, progress callback function, fired periodically before the load is completed.

@returns An instance of `IOHandler`.

```

export function http(path: string, loadOptions?: LoadOptions): IOHandler {

Deprecated. Use `tf.io.http`.

```

Creates an IOHandler that loads model artifacts from memory.

When used in conjunction with `tf.loadLayersModel`, an instance of `tf.LayersModel` (Keras-style) can be constructed from the loaded artifacts.

```

const model = await tf.loadLayersModel(tf.io.fromMemory(modelTopology, weightSpecs, weightData));

```

@param modelArtifacts a object containing model topology (i.e., parsed from the JSON format).

@param weightSpecs An array of `WeightsManifestEntry` objects describing the names, shapes, types, and quantization of the weight data.

@param weightData A single `ArrayBuffer` containing the weight data, concatenated in the order described by the `weightSpecs`.

@param trainingConfig Model training configuration.

these blocks with the "batch" dimension (0) such that in the output, the spatial dimensions [1, ..., M] correspond to the position within the grid and the batch dimension combines both the position within a spatial block and the original batch position. Prior to division into blocks, the spatial dimensions of the input are optionally zero padded according to paddings. See below for a precise description.

```

tf.tensor4d([1, 2, 3, 4], [1, 2, 2, 1]);
const blockSize = [2, 2];
const paddings = [[0, 0], [0, 0]];
x.spaceToBatchND(blockShape, paddings).print();

```

N-D with x.shape = [batch] + spatialShape + remainingShape, where spatialShape has M dimensions. @param blockSize A 1-D array. Must have shape [M], all values must be >= 1. @param paddings A 2-D array. Must have shape [M, 2], all values must be >= 0. paddings[i] = [padStart, padEnd] specifies

the amount to zero-pad from input dimension i + 1, which corresponds to spatial dimension i. It is required that (inputShape[i + 1] + padStart + padEnd) % blockSize[i] === 0. This operation is equivalent to the following steps:

- Zero-pad the start and end of dimensions [1, ..., M] of the input according to paddings to produce padded of shape paddedShape.
- Reshape padded to reshapedPadded of shape: [batch] + [paddedShape[1] / blockSize[0], blockSize[0], ..., paddedShape[M] / blockSize[M-1], blockSize[M-1]] + remainingShape.
- Permute dimensions of reshapedPadded to produce permutedReshapedPadded of shape: blockSize + [batch] + [paddedShape[1] / blockSize[0], ..., paddedShape[M] / blockSize[M-1]] + remainingShape.
- Reshape permutedReshapedPadded to flatten blockSize into the batch dimension, producing an output tensor of shape: [batch * prod(blockShape)] + [paddedShape[1] / blockSize[0], ..., paddedShape[M] / blockSize[M-1]] + remainingShape.

// A Javascript implementaion of
Richard Brent's Xorgens xor4096 algorithm.
// This fast non-cryptographic random number generator is
designed for
// use in Monte-Carlo algorithms. It combines a long-period xorshift
generator with a Weyl
generator, and it passes all common batteries
of stastical tests for randomness while consuming only a few
nanoseconds
for each prng generated. For background on the generator, see Brent's
paper: "Some long-
period random number generators using shifts and xors."
http://arxiv.org/pdf/1004.3115v1.pdf
Usage:
var xor4096 = require('xor4096');
random = xor4096(1); // Seed with int32 or
string.
assert.equal(random(), 0.1520436450538547); // (0, 1) range, 53 bits.
assert.equal(random.int32(), 1806534897); // signed int32, 32 bits.
// For nonzero numeric keys, this impelementation provides a

```

sequence identical to that by Brent's xorgens 3 implementation in C. This implementation also provides for initializing the generator with string seeds, or for saving and restoring the state of the generator. On Chrome, this prng benchmarks about 2.1 times slower than Javascript's built-in Math.random().

 * `@param dataFormat` An optional string from: `"NHWC"`, `"NCHW"`. Defaults to `"NHWC"`.

Specify the data format of the input and output data. With the default format `"NHWC"`, the data is stored in the order of: `[batch, height, width, channels]`. Only `"NHWC"` is currently supported.
 * `@param dilations` The dilation rates: `[dilationHeight, dilationWidth]` in which we sample input values across the height and width dimensions in atrous convolution. Defaults to `[1, 1]`. If `dilations` is a single number, then `dilationHeight == dilationWidth`. If it is greater than 1, then all values of `strides` must be 1.
 * `@param dimRoundingMode` A string from: `'ceil'`, `'round'`, `'floor'`. If none is provided, it will default to `truncate`.
 * `@param bias` Tensor to be added to the result.
 * `@param activation` Name of activation kernel (defaults to `'linear'`) to be applied after `biasAdd`.
 * `@param preluActivationWeights` Tensor of prelu weights to be applied as part of a `'prelu'` activation, typically

the same shape as `x`.
 * `@param leakyreluAlpha` Optional. Alpha to be applied as part of a `'leakyrelu'` activation.
 * `@function fusedConv2d`

@param obj An object with the following properties:

- x** The input tensor, of rank 4 or rank 3, of shape `[batch, height, width, inChannels]`. If rank 3, batch of 1 is assumed.
- filter** The filter tensor, rank 4, of shape `[filterHeight, filterWidth, inChannels, channelMultiplier]`.
- strides** The strides of the convolution: `[strideHeight, strideWidth]`. If strides is a single number, then `strideHeight == strideWidth`.
- pad** The type of padding algorithm. - `'same'` and stride 1: output will be of same size as input, regardless of filter size. - `'valid'`: output will be smaller than input if filter is larger than 1x1.
- For more info, see this guide: https://www.tensorflow.org/api_guides/python/nn#Convolution
- dilations** The dilation rates: `[dilationHeight, dilationWidth]` in which we sample input values across the height and width dimensions in atrous convolution. Defaults to `[1, 1]`. If `rate` is a single number, then `dilationHeight == dilationWidth`. If it is greater than 1, then all values of `strides` must be 1.
- dataFormat**: An optional string from: `'NHWC'`, `'NCHW'`. Defaults to `'NHWC'`. Specify the data format of the input and output data. With the default format `'NHWC'`, the data is stored in the order of: [batch, height, width, channels]. Only `'NHWC'` is currently supported.
- dimRoundingMode** A string from: `'ceil'`, `'round'`, `'floor'`. If none is provided, it will default to `truncate`.
- bias** Tensor to be added to the result.
- activation** Name of activation kernel (defaults to `'linear'`).
- preluActivationWeights** Tensor of prelu weights to be applied as part of a `'prelu'` activation, typically the same shape as `x`.
- leakyreluAlpha** Optional. Alpha to be applied as part of a `'leakyrelu'` activation.

@param initialAccumulatorValue Starting value
for the accumulators, must be positive.

This will be the shape for an\n // intermediate TensorBuffer (see inputBuffer

```

below) to allow us to extract

the given axis. To demonstrate how it works, consider the following example: Input: a 3D tensor, with shape [1, 2, 3] along axis 2 (the last axis). Along axis 2, we expect to extract 3 tensors: [1,4], [2,5], [3,6]. For this example, newShape would be: [2, 3, 1], where 2 is calculated from 1\*2. The re-shaped data would look like: [1], [2], [3], [4], [5], [6]. Then, we can construct a 3-level nested loop by the following dimension order to extract the values along the axis (dimension1):

```
// m: dimension0 // 0,1 (newShape[0]) // n: dimension2 // 0 (newShape[2])
// m, i, n ----- Iteration 0: data at [0, 0, 0] => "1" Iteration 1:
// data at [1, 0, 0] => "4" We got [1,4] Iteration 2: data at [0, 1, 0] => "2" Iteration 3: data at [1, 1, 0]
// => "5" We got [2,5] Iteration 4: data at [0, 2, 0] => "3" Iteration 5: data at [1, 2, 0] => "6" We
// got [3,6]
const newShape = [1, shape[0], 1];
for (let i = 0; i < $axis; i++) {
 newShape[0] *= shape[i];
}
newShape[1] = shape[$axis];
for (let i = $axis + 1; i < shape.length; i++) {
 newShape[2] *= shape[i];
}
// A map from unique elements (their string representations) to their values in "indices" (below).
